The radio/gamma-ray connection in Active Galactic Nuclei in the Fermi era

M. Giroletti INAF Istituto di Radioastronomia

and V. Pavlidou, A. Reimer on behalf of the Fermi-LAT collaboration

Roma, X Congresso Nazionale AGN, 13/9/2012

- 1. General background EGRET and Fermi
- 2. Open questions
- 3. Dataset and method
- 4. Results
- 5. Summary

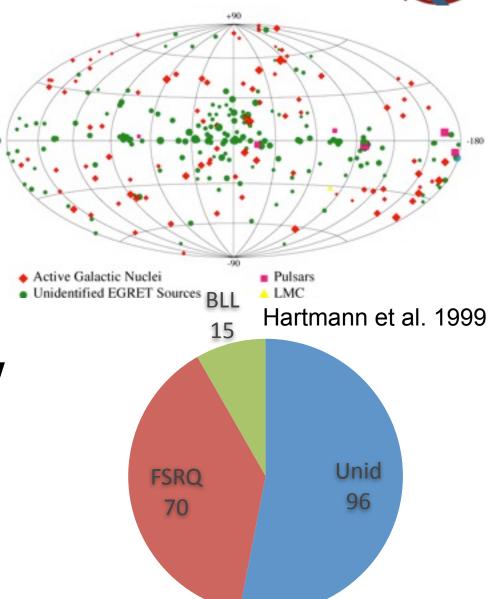

• EGRET 1991-1999

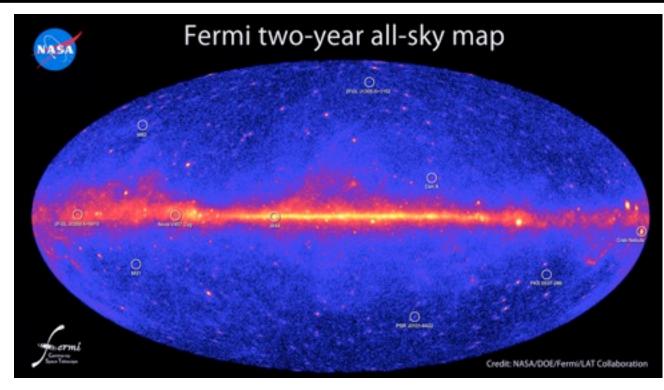

Gamma-ray pace Telescope

- Most high galactic latitude sources remained unidentified
- All the identified ones were radio loud, almost all blazars, and mostly FSRQ; very few BL Lacs, only 2 HBLs

From EGRET to Fermi

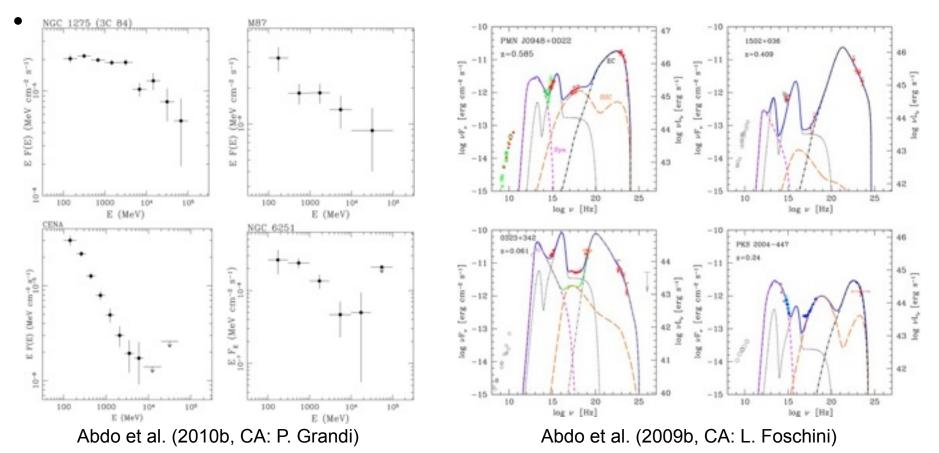

- EGRET: 66 blazar (+27 I.c., FSRQ:BLL=4.7)
- LBAS: 106 AGN (FSRQ:BLL=1.4)

Gamma-ray pace Telescope

- 1LAC: 709 AGN (FSRQ:BLL=1.0)
- 2LAC: 1017 AGN (FSRQ:BLL=0.8)
- Only a few unidentified sources remain at high fluxes
- Gamma-ray sources continue to be associated to radio loud objects

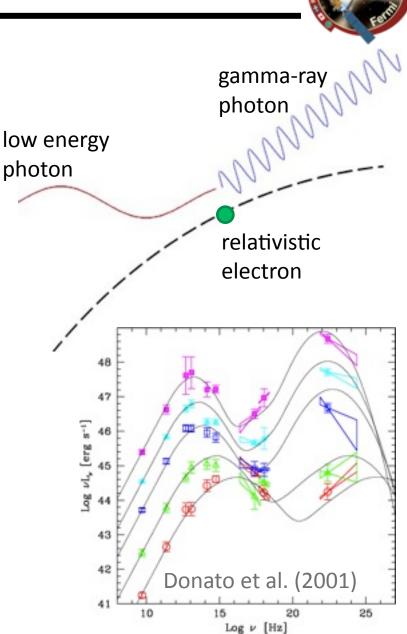

- Vast majority (97.3%) of Fermi h.l. associated sources are blazars
- Non blazar sources are typically misaligned blazars (MAGN), or very blazar-like sources (RL NLS1)
- Only truly non blazar sources are Cen A lobes and 2 starbursts

Gamma-ray pace Telescope

- some connection between radio and gamma-ray properties is expected!
- observationally, all EGRET AGNs are radio loud, differently from most X-ray QSOs
- the blazar sequence was originally devised on the basis of the radio luminosity
- evidence or not of flux-flux, Lum-Lum correlations is a debated issue
 - Stecker et al. (1993), Mücke et al. (1997), Bloom (2008), etc.
 - bias, variability, number of sources, etc.

Radio/gamma-ray connection in the Fermi era

- Big questions
 - is there a correlation between radio and gamma-ray flux in AGNs?
 - is it also significant?
 - does it depend on simultaneity?
 - does it depend on blazar type?
 - does it depend on energy band?
- See also works from Kovalev et al. (2009), Ghirlanda et al. (2010, 2011), Mahony et al. (2010)

Radio/gamma-ray connection in the Fermi era

Ingredients

pace Telescope

- Gamma-rays
 - 599 sources characterized in gamma rays by LAT in the 1LAC (flux, photon index, and flux in bands)
- Radio
 - <u>ALL SOURCES</u> with <u>ARCHIVAL</u> radio data of <u>CORE REGION</u> (freq. 8.4 GHz, ang. resolution ~ 0.2", e.g. from CRATES, Healey et al. 2007)
 - 199 brightest and northern also with <u>REGULAR AND SIMULTANEOUS</u> monitoring (~twice per week) at 15 GHz (from OVRO radio telescope, see Richards et al. 2011)
- machinery to assess significance of flux-flux correlations – NB: significance and strength are different things! (Pavlidou et al., 2012)

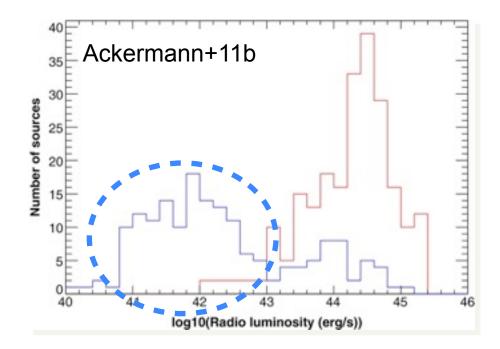

- 1. Include ALL gamma-ray AGNs (typically, the faintest ones were not considered in previous works)
- 2. Use both archival and simultaneous radio data
- 3. Assess statistical significance with dedicated tools

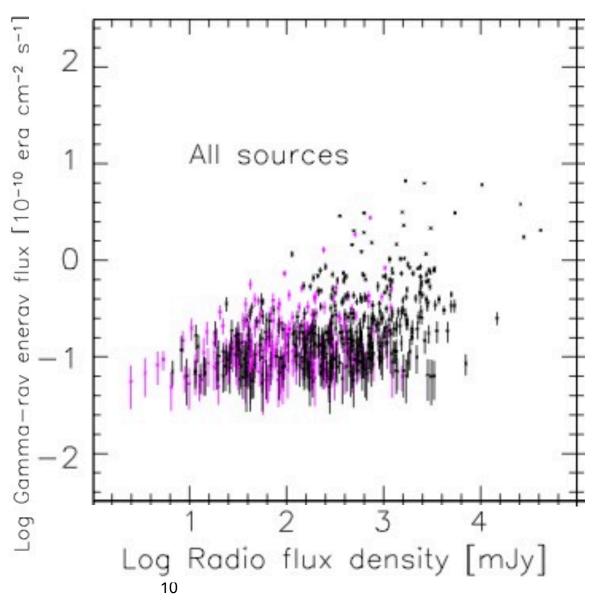

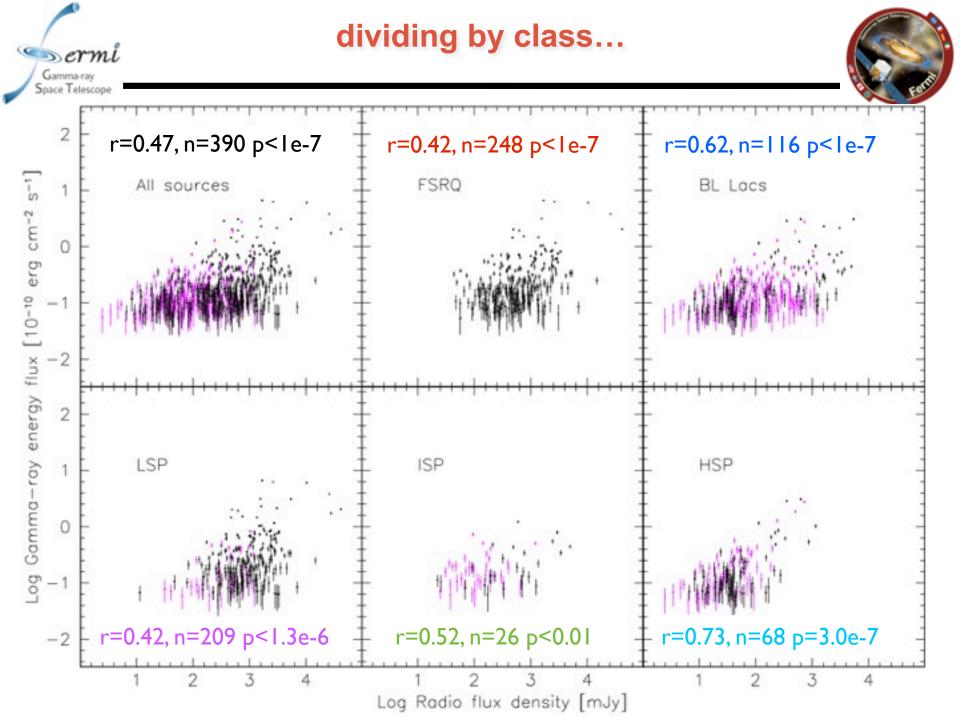

Results: Ackermann et al. 2011, ApJ 741 30

- All 599 1LAC clean sources
- black: with redshift
- magenta: without redshift
- <u>r=0.47</u>
- <u>P<1e-7</u>

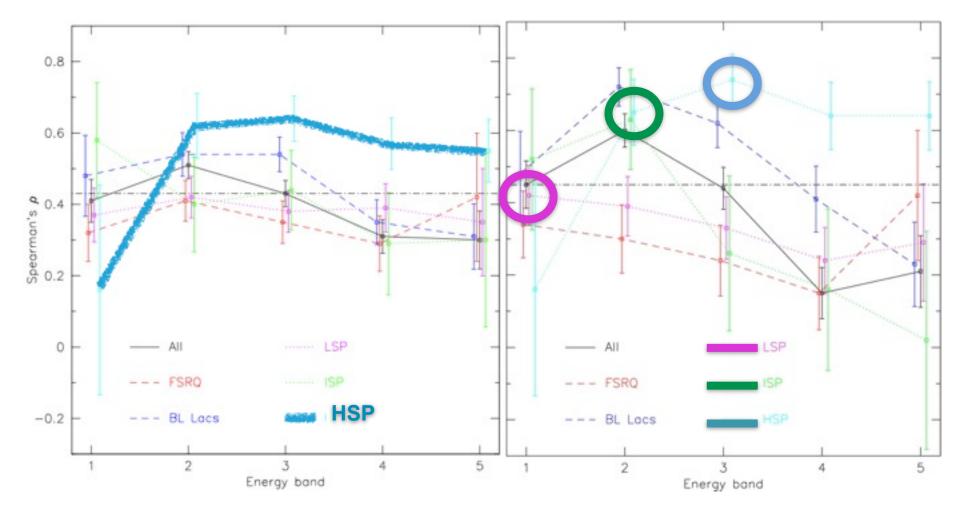

- Timing
 - Considering the subset of sources regularly monitored by OVRO, the correlation coefficient and the significance improve when considering simultaneous vs archival data
- Blazar types
 - BL Lacs (r=0.46) show a moderately stronger correlation than FSRQs (r=0.39)
 - each sub-class (FSRQ and BLL) independently still shows very high significance of a correlation (p<1e-7)
 - HSP blazars have the stronger correlation among the various SEDbased classification
- Energy bands
 - Not all LAT energy bands correlate with radio with the same strengths
 - LSP have strongest correlation in band 0.3-1 GeV, ISP in 1-3 Gev, HSP in 3-10 GeV
 - ...but significance is marginal so far

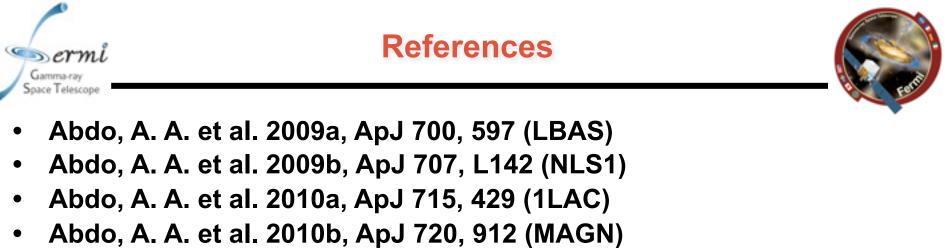

Conclusions

- Big *questions* answers:
 - is there a correlation between radio and gamma-ray flux in AGNs?
 - YES
 - is it also significant?
 - YES
 - does it depend on simultaneity?
 - YES
 - does it depend on blazar type?
 - maybe YES
 - does it depend on energy band?
 - maybe YES

EXTRA SLIDES

LAT Bright AGN Sample (LBAS, Abdo et al. 2009, ApJ 700, 597)

- 125 non-pulsar sources at |b|>10°
 - Only 9 unassociated (3EG: 96/181 at |b|>10°)
 - Much more balanced FSRQ/BLL ratio: 58/42 (including 7 HBLs)
 - (plus 4 of uncertain type and 2 radiogalaxies: Cen A, NGC1275)
- Unique Fermi features and FSRQ/BLL characterizations:
 - energy range: different spectral properties
 - Sensitivity: confirms different redshift distributions
 - Positional accuracy: counterparts identification and MWL properties

• LBAS results were restricted to

pace Telescope

- 3 months of gamma-ray data
- TS>100 (highest confidence gamma-ray sources)
- Fermi has continued its operation in survey mode with unique characteristics:
 - Sensitivity: include the weakest gamma-ray (and radio?) sources
 - Field of view: gather data from as large sky area as possible
 - Spectral range: collect and discuss soft (radio bright?) and hard (radio weak?) sources
- Milestones after 11 months of data collection
 - the 1FGL (first Fermi-LAT catalog), which contains and characterizes 1451 sources (Abdo et al. 2010, ApJS 188, 405)
 - the 1LAC (first catalog of Fermi-LAT detected AGNs), which includes 671 gamma-ray sources statistically associated to high latitude AGNs (Abdo et al. 2010, ApJ 715, 429)

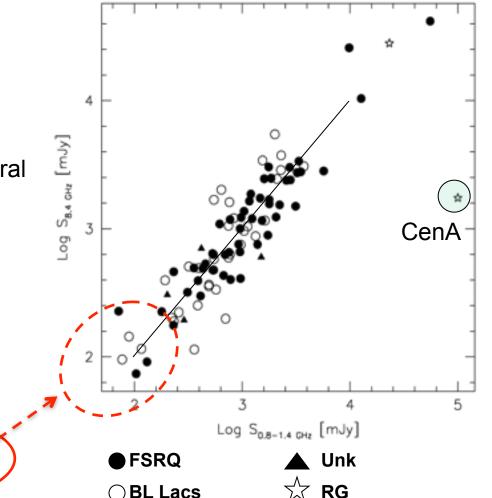

- Based on LBAS (bright Fermi AGNs)
- Flux plane is not subject to distance bias
 - Low frequency from NVSS (1.4) GHz) or SUMSS (0.8 GHz)
 - High frequency typically from CRATES (8.4 GHz, or NED)
- another representation of the spectral index flatness
 - little to none extended radio emission

New BL Lacs

sample fills in here

except Cen A!

erm Gamma-ray pace Telescope

 \bigcirc BL Lacs

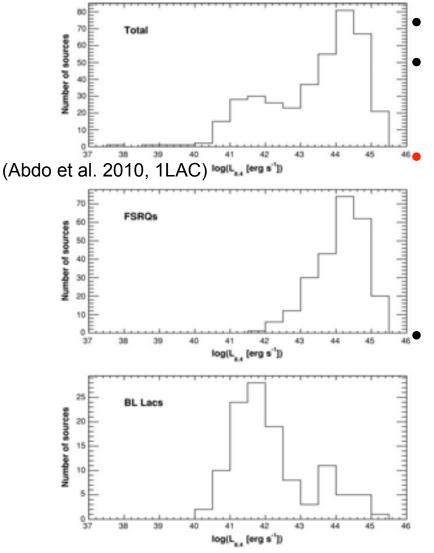

- Caveat: Distance dependence stretches distribution
- All cores more luminous than expected for RG of same P_{low}
 - Doppler boost!
 - even more if one could subtract core from truly extended emission
 - indeed, extended radio emission of LBAS sources could be as low as 10²³ W Hz⁻¹
 - CenA well behaved: fair amount of extended radio emission
- Radio luminosity $L_r = vL(v)$ span a broad range $10^{39.1} < L_r < 10^{45.3}$ erg s⁻¹, (v=8.4 GHz)
 - with different distributions for BL Lacs and FSRQ:
 - FSRQ: $LogL_r = 44.4 \pm 0.6$ [erg s⁻¹]
 - BL Lacs: LogL_r=42.8±1.1 [erg s⁻¹]

1LAC: Radio luminosity

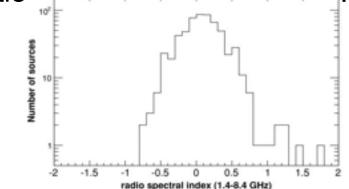

- $L_r = vL(v), v = 8.4 \text{ GHz}$
- Radio luminosity L_r is typically 10⁴¹-10⁴⁵ erg s⁻¹
 - but it can be as low as 10³⁷ erg s⁻¹

FSRQ are clustered at higher luminosities, while BL Lacs follow a broader distribution down to 10⁴⁰ erg s⁻¹

- FSRQ: 44.1 +/- 0.7 [erg s⁻¹]
- BLLacs: 42.2 +/- 1.1 [erg s⁻¹]

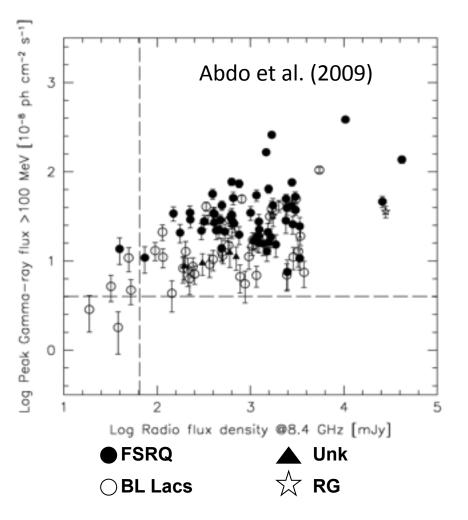

Unknown type blazars and some BL Lacs lack redshift so actual distribution may be a little different

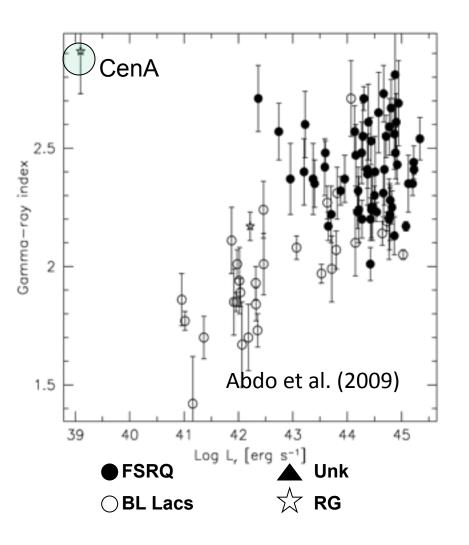

- Radio: CRATES/NED flux density at 8.4 GHz
- Gamma-ray: Fermi-LAT peak flux at E>100 Mev in 3 months
- Spearman's rank correlation coefficient: r=0.42, for 106 elements, but...
 - Do few data points drive correlation?
 - BL Lacs and FSRQ sample rather different regions
 - FSRQ: 57 sources, r=0.19, BL Lacs: 42 sources, r=0.49
 - Total without the most extreme data points goes down to r=0.24 (12% of the sample)
- Significance difficult to claim. Issues:
 - Variability, extended radio emission
 - Selection effects?

- Only sources with known redshift
 - K-corrected
- FSRQs: largest Lr, softer indices
- BL Lacs: lower Lr, harder indices
- RGs: 3C84 BL Lac-like, Cen A well displaced

 Two groups showing some correlation when considered independently, show the opposite behavior when considered as one set.
